Escuela de Ciencias Aplicadas e Ingeniería

Next token prediction

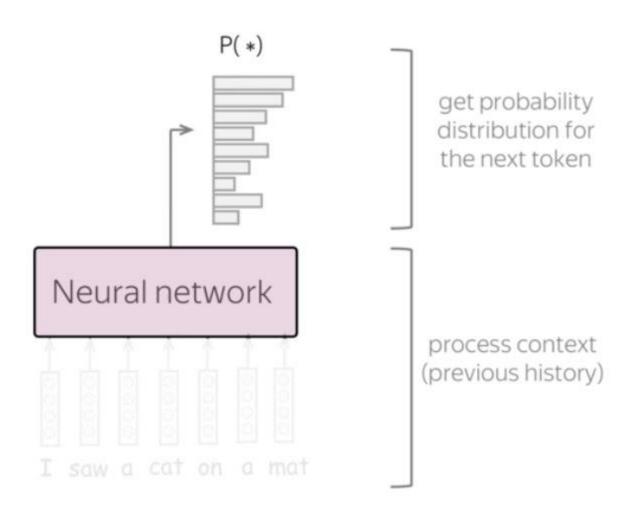

- Model $p\theta(w_t \mid w_{1:t-1})$, the probability distribution over words given their preceding context.
- There is a lot of data for this! (In English!)
- Pre-training using language modeling:
 Train a neural network to perform language modeling on a large amount of text.
- Save the network's parameters.

Next token prediction

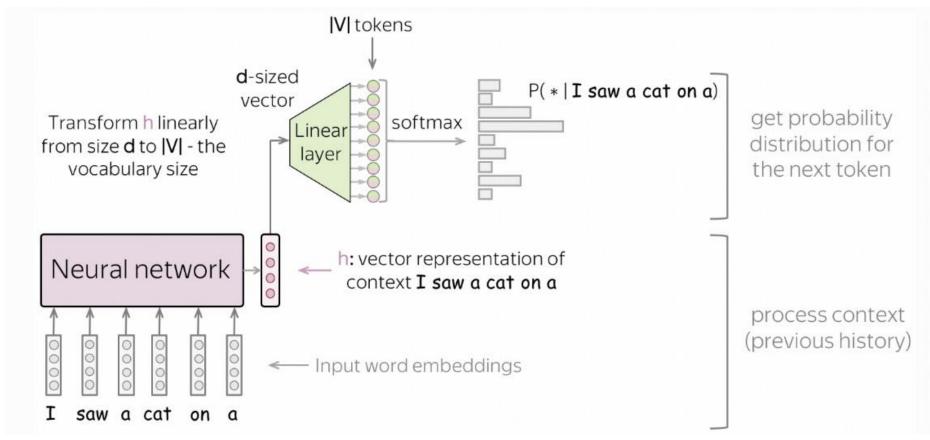

This is classification! We can think of neural language models as neural classifiers. They classify prefix of a text into |V| classes, where the classes are vocabulary tokens.

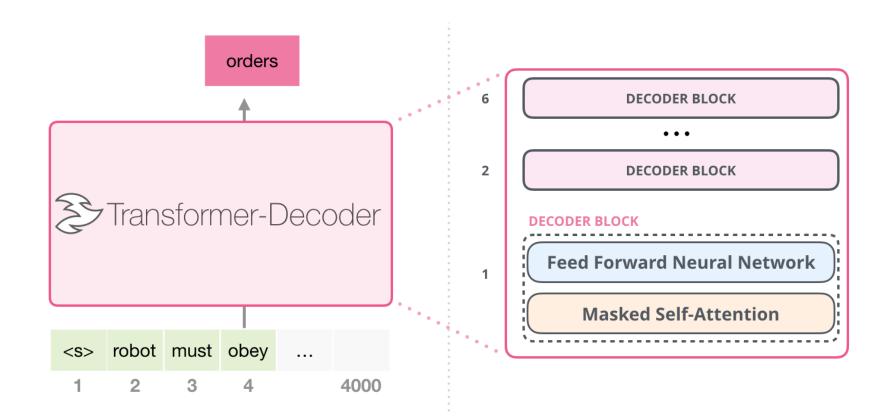

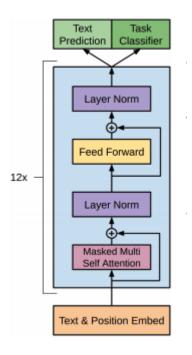

- Feed word embedding for previous (context) words into a network;
- get vector representation of context from the network;
- from this vector representation, predict a probability distribution for the next token

Grouped Query Attention

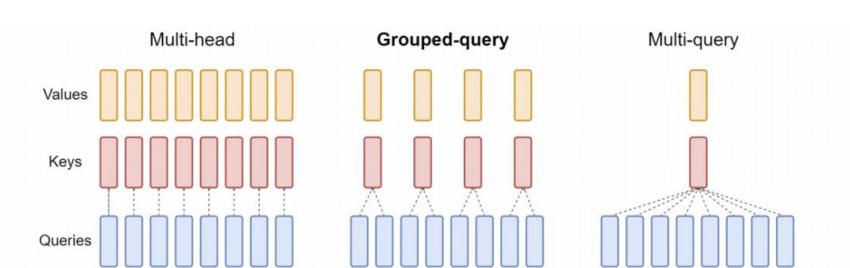

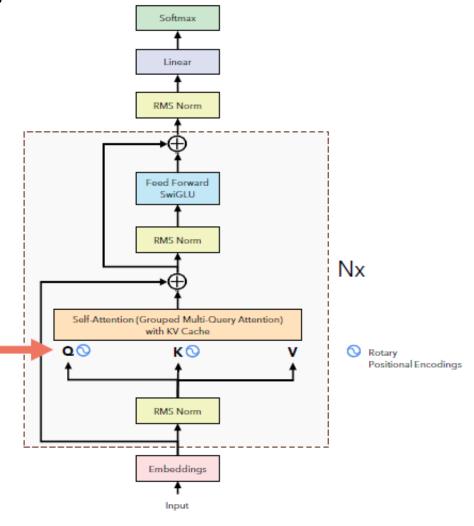

Figure 2: Overview of grouped-query method. Multi-head attention has H query, key, and value heads. Multi-query attention shares single key and value heads across all query heads. Grouped-query attention instead shares single key and value heads for each *group* of query heads, interpolating between multi-head and multi-query attention.

- Rotary Positional Encodings apply only to queries
 (q) and keys (k), not to values (v).
- In rotary encodings, they are applied after multiplying q and k by matrix W, whereas in a vanilla transformer, they are applied before.

- The dot product used in the attention mechanism is a type of inner product, which
 can be considered a generalization of the dot product
- Can we find an inner product between the two vectors q (query) and k (key) used in the attention mechanism that depends only on the two vectors and the relative distance of the token they represent?

Under the case of d = 2, we consider two-word embedding vectors x_q , x_k corresponds to query and key and their position m and n, respectively. According to eq. (1), their position-encoded counterparts are:

$$\mathbf{q}_m = f_q(\mathbf{x}_q, m),$$

$$\mathbf{k}_n = f_k(\mathbf{x}_k, n),$$
(20)

where the subscripts of q_m and k_n indicate the encoded positions information. Assume that there exists a function g that defines the inner product between vectors produced by $f_{\{q,k\}}$:

$$\boldsymbol{q}_{m}^{\mathsf{T}}\boldsymbol{k}_{n} = \langle f_{q}(\boldsymbol{x}_{m}, m), f_{k}(\boldsymbol{x}_{n}, n) \rangle = g(\boldsymbol{x}_{m}, \boldsymbol{x}_{n}, n - m), \tag{21}$$

• We can define a function ${\bf g}$ as follows, which depends only on the two embedding vectors ${\bf q}$ and ${\bf k}$ and their relative distance:

$$egin{align} f_q(x_m,m) &= \left(W_q x_m
ight) e^{im heta} \ f_k(x_n,n) &= \left(W_k x_n
ight) e^{in heta} \ g(x_m,x_n,m-n) &= \mathrm{Re}\left[\left(W_q x_m
ight) \left(W_k x_n
ight)^* e^{i(m-n) heta}
ight] \end{aligned}$$

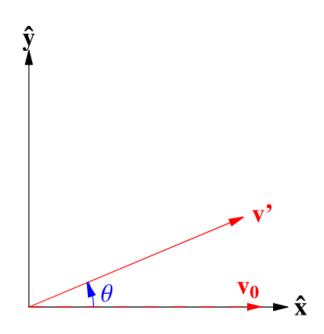

• Using euler:

$$f_{(q,k)}(x_m, m) = \begin{pmatrix} \cos m\theta & -\sin m\theta \\ \sin m\theta & \cos m\theta \end{pmatrix} \begin{pmatrix} W_{q,k}^{(11)} & W_{q,k}^{(12)} \\ W_{q,k}^{(21)} & W_{q,k}^{(22)} \end{pmatrix} \begin{pmatrix} x_m^{(1)} \\ x_m^{(2)} \end{pmatrix}$$

Rotation matrix in a 2D space, hence the name rotary positional encodings.

In \mathbb{R}^2 , consider the matrix that rotates a given vector \mathbf{v}_0 by a counterclockwise angle θ in a fixed coordinate system. Then

$$\mathsf{R}_{\theta} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix},\tag{1}$$

SO

$$\mathbf{v}' = \mathsf{R}_{\theta} \, \mathbf{v}_0.$$

• Since the matrix is **sparse**, it is not convenient to use it for computing positional encodings.

$$f_{\{q,k\}}(\boldsymbol{x}_m, m) = \boldsymbol{R}_{\Theta,m}^d \boldsymbol{W}_{\{q,k\}} \boldsymbol{x}_m$$
(14)

where

$$\mathbf{R}_{\Theta,m}^{d} = \begin{pmatrix}
\cos m\theta_{1} & -\sin m\theta_{1} & 0 & 0 & \cdots & 0 & 0 \\
\sin m\theta_{1} & \cos m\theta_{1} & 0 & 0 & \cdots & 0 & 0 \\
0 & 0 & \cos m\theta_{2} & -\sin m\theta_{2} & \cdots & 0 & 0 \\
0 & 0 & \sin m\theta_{2} & \cos m\theta_{2} & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \cdots & \cos m\theta_{d/2} & -\sin m\theta_{d/2} \\
0 & 0 & 0 & \cdots & \sin m\theta_{d/2} & \cos m\theta_{d/2}
\end{pmatrix}$$
(15)

is the rotary matrix with pre-defined parameters $\Theta = \{\theta_i = 10000^{-2(i-1)/d}, i \in [1, 2, ..., d/2]\}$. A graphic illustration of RoPE is shown in Figure 1. Applying our RoPE to self-attention in Equation 2, we obtain:

$$\boldsymbol{q}_{m}^{\mathsf{T}}\boldsymbol{k}_{n} = (\boldsymbol{R}_{\Theta,m}^{d}\boldsymbol{W}_{q}\boldsymbol{x}_{m})^{\mathsf{T}}(\boldsymbol{R}_{\Theta,n}^{d}\boldsymbol{W}_{k}\boldsymbol{x}_{n}) = \boldsymbol{x}^{\mathsf{T}}\boldsymbol{W}_{q}R_{\Theta,n-m}^{d}\boldsymbol{W}_{k}\boldsymbol{x}_{n}$$
(16)

where $\mathbf{R}^d_{\Theta,n-m} = (\mathbf{R}^d_{\Theta,m})^\intercal \mathbf{R}^d_{\Theta,n}$. Note that \mathbf{R}^d_{Θ} is an orthogonal matrix, which ensures stability during the process of encoding position information. In addition, due to the sparsity of R^d_{Θ} , applying matrix multiplication directly as in Equation (16) is not computationally efficient; we provide another realization in theoretical explanation.

• Given a token with the embedding vector \mathbf{x} and the token's position \mathbf{m} within the sentence, this is how we compute positional encodings for the token.

3.4.2 Computational efficient realization of rotary matrix multiplication

Taking the advantage of the sparsity of $\mathbf{R}_{\Theta,m}^d$ in Equation (15), a more computational efficient realization of a multiplication of R_{Θ}^d and $\mathbf{x} \in \mathbb{R}^d$ is:

$$\boldsymbol{R}_{\Theta,m}^{d}\boldsymbol{x} = \begin{pmatrix} x_{1} \\ x_{2} \\ x_{3} \\ x_{4} \\ \vdots \\ x_{d-1} \\ x_{d} \end{pmatrix} \otimes \begin{pmatrix} \cos m\theta_{1} \\ \cos m\theta_{2} \\ \cos m\theta_{2} \\ \vdots \\ \cos m\theta_{d/2} \\ \cos m\theta_{d/2} \end{pmatrix} + \begin{pmatrix} -x_{2} \\ x_{1} \\ -x_{4} \\ x_{3} \\ \vdots \\ -x_{d-1} \\ x_{d} \end{pmatrix} \otimes \begin{pmatrix} \sin m\theta_{1} \\ \sin m\theta_{1} \\ \sin m\theta_{2} \\ \sin m\theta_{2} \\ \vdots \\ \sin m\theta_{d/2} \\ \sin m\theta_{d/2} \end{pmatrix}$$
(34)

- Upper bound for the inner product decreases as token distance increases.
- Rotary Positional Encodings reduce interaction strength between distant tokens.

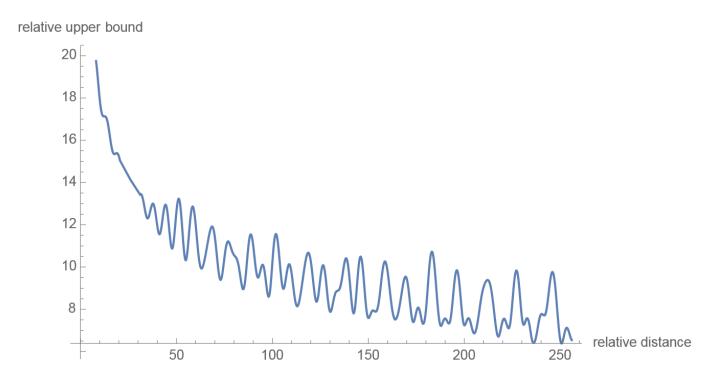

Figure 2: Long-term decay of RoPE.

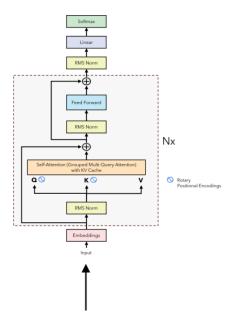

Inference Optimization: We only need the last token at each step.

Challenge: The model still requires all previous tokens as context.

Solution: Use a KV (Key-Value) Cache to avoid redundant computations.

- Continue training the language model (LM) on the output.
- Issue: Optimization method can be memory-intensive depending on the optimizer.
- Example: Training a 65B parameter model using 16-bit mixed precision (FP16)
 (Rajbhandari et al., 2019).

1000-1400GB of GPU memory!

Supervised Fine-Tuning (SFT) Data Examples

Summarization

Input:

The Eiffel Tower, built in 1889, is one of the most famous landmarks in the world. Located in Paris, it stands at 330 meters tall and attracts millions of visitors each year.

Output (Summary):

The Eiffel Tower is a famous 330-meter-tall landmark in Paris, built in 1889.

Question Answering (QA)

Context:

The Great Wall of China is a historic fortification built to protect Chinese states from invasions. Construction started as early as the 7th century BC and continued for centuries.

- ? Question: When did the construction of the Great Wall begin?
- Answer: The 7th century BC.

Instruction Following

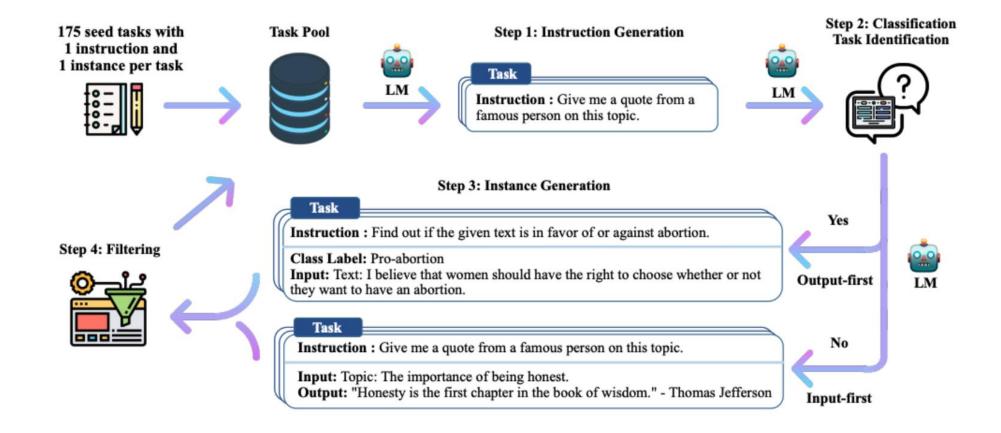

Translate the following sentence into French: "The weather is beautiful today."

Response: Le temps est magnifique aujourd'hui.

 It is possible to automatically generate instruction tuning datasets, e.g. self-instruct (Wang et al. 2022)

Alpaca

 Generating high-quality instruction tuning dataset with Self-Instruct using OpenAI text-devinci-003

Step 1: Start with LLaMA 7B

• Used Meta's LLaMA 7B as the base model.

Step 2: Generate Synthetic Data Using GPT-3.5

- Started with 175 human-written instruction examples.
- Prompted text-davinci-003 (OpenAl API) to generate 52,000 diverse instructions & responses.
- Cost of API calls: Only ~\$500 USD 🄞 (compared to millions for human annotation).

Step 3: Fine-Tune LLaMA on This Data

• The synthetic instruction dataset was used to fine-tune LLaMA 7B, turning it into Alpaca.

Step 4: Model Evaluation

- Researchers tested Alpaca vs. text-davinci-003 on various tasks.
- Alpaca exhibited similar instruction-following performance but at a fraction of the cost.

Further compress memory requirements for training by 4-bit quantization of the model

Deep learning models, such as LLaMA 2, have billions of parameters, each stored as floating-point numbers (typically FP32 or FP16). This leads to huge memory requirements.

•Example:

- LLaMA 2 7B parameters
- Each parameter stored as FP32 (4 bytes per value)
- Total memory needed:

$7 imes 10^9 imes 32$	=28GB
8×10^{9}	- 20GD

Binary	Number
000	0
001	1
010	2
011	3
100	4
101	5
110	6
111	7

$$110 = 1 \times 2^2 + 1 \times 2^1 + 0 \times 2^0 = 6$$

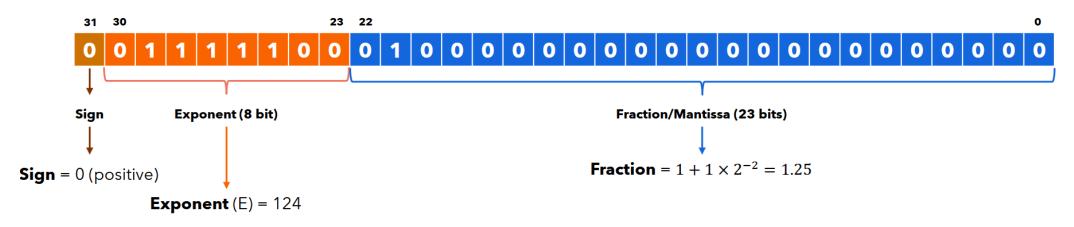

By reducing parameter precision (e.g., FP32 → INT8), we can **cut memory usage** dramatically, enabling deployment on **smaller GPUs** and **faster inference**.

Decimal numbers are just numbers that also include negative powers of the base. For example:

$$85.612 = 8 \times 10^{1} + 5 \times 10^{0} + 6 \times 10^{-1} + 1 \times 10^{-2} + 2 \times 10^{-3}$$

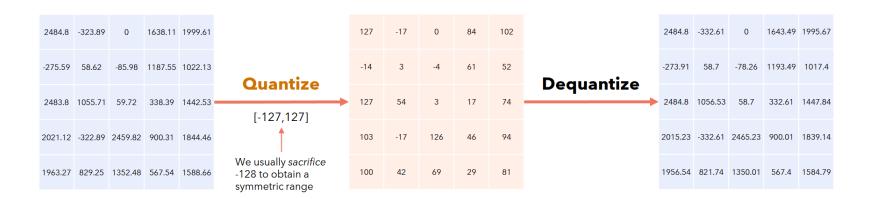

The IEEE-754 standard defines the representation format for floating point numbers in 32 bit.

Value =
$$(-1)^{sign} \times 2^{(E-127)} \times (1 + \sum_{i=1}^{23} b_{23-i} 2^{-i}) = (+1) \times 2^{-3} \times 1.25 = +0.15625$$

Modern GPUs also support a 16-bit floating point number, with less precision.

Step 1: Define Quantization Scale and Zero-Point

To convert FP32/FP16 values to INT8/INT4, we define:

Scale (S): A small floating-point number that helps reconstruct the original value.

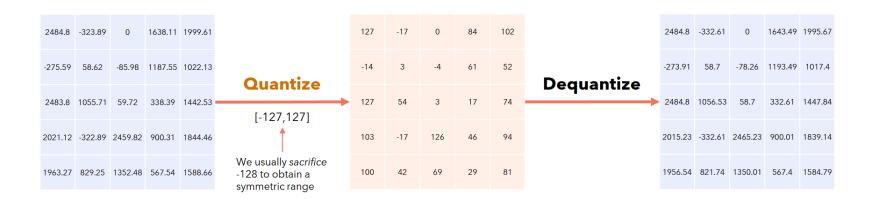

Zero-point (Z): An integer shift to handle negative values.

FP16 Value (x)	Scale (S)	Zero-Point (Z)	Quantized INT8 (q)
0.45	0.1	128	132
-0.30	0.1	128	125
1.20	0.1	128	140

$$q = \operatorname{round}\left(rac{x}{S} + Z
ight)$$

- q = quantized integer value (e.g., INT8, INT4)
- ullet x = original floating-point value
- S = scale factor
- Z = zero-point

Step 2: Dequantization process

Since computation in hardware (e.g., matrix multiplications) happens in lower precision, **dequantization** is needed to recover approximate floating-point values.

Quantized INT8 (q)	Scale (S)	Zero-Point (Z)	Dequantized FP16 (x')
132	0.1	128	0.4
125	0.1	128	-0.3
140	0.1	128	1.2

$$x'=(q-Z) imes S$$

- x' = dequantized floating-point value (approximate x)
- q = quantized value (e.g., INT8)
- S = scale factor
- Z = zero-point
