Creating token embeddings

Embedding layers: An efficient way of performing matrix multiplication when working with one-hot encoded vectors.

```
import torch
torch.manual_seed(123);

idx = torch.tensor([2, 3, 1]) # 3 training examples

num_idx = max(idx)+1
out_dim = 5

Input dimension of a one-hot encoded vector is the number of indices
(the highest index + 1)
```

```
import torch
torch.manual seed(123);
idx = torch.tensor([2, 3, 1]) # 3 training examples
num_idx = max(idx)+1
out_dim = 5
embedding = torch.nn.Embedding(num_idx, out_dim)
embedding(idx)
tensor([[ 0.6957, -1.8061, -1.1589, 0.3255, -0.6315],
                                                              Each training example has
        [-2.8400, -0.7849, -1.4096, -0.4076, 0.7953],
                                                                   5 feature values
        [1.3010, 1.2753, -0.2010, -0.1606, -0.4015]],
       grad_fn=<EmbeddingBackward0>)
```

Creating token embeddings

Sentence embeddings

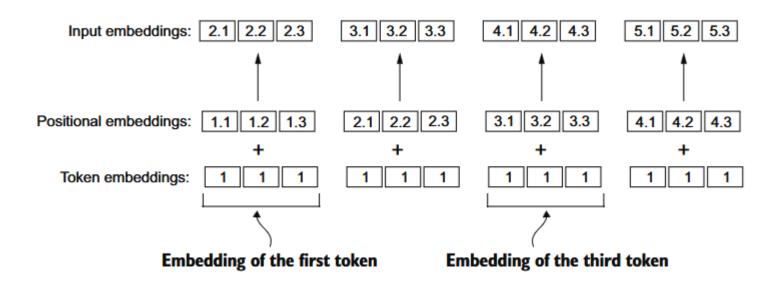

Task: Aggregate token embeddings in a sentence to form a unique sentence representation.

Encoding word positions

OpenAI: Positional embeddings are learnable parameters.

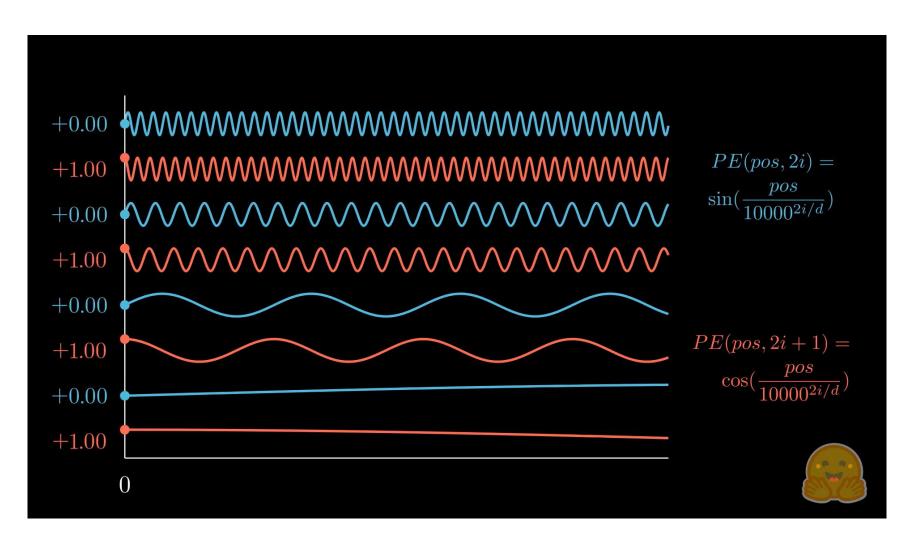

Llama, DeepSeek: Rotational Positional Embeddings - RoPE

Bert: Sinusoidal Positional Embeddings

Sinusoidal positional embeddings

$$egin{aligned} PE(pos,2i) &= \sin\left(rac{pos}{10000^{rac{2i}{d}}}
ight) \ PE(pos,2i+1) &= \cos\left(rac{pos}{10000^{rac{2i}{d}}}
ight) \end{aligned}$$

Rotary Positional Embeddings (RoPE)

Escuela de **Ciencias Aplicadas** e Ingeniería

Fundamental idea: we want the dot product of embeddings to result in a function of relative position:

$$f_q(\mathbf{x}_m, m) \cdot f_k(\mathbf{x}_n, n) = g(\mathbf{x}_m, \mathbf{x}_n, m - n)$$

ROFORMER: ENHANCED TRANSFORMER WITH ROTARY POSITION EMBEDDING

In summary, RoPE uses trigonometry to come up with a function that satisfies this property

$$R_{\Theta,m}^{d}\mathbf{x} = \begin{pmatrix} x_{1} \\ x_{2} \\ x_{3} \\ x_{4} \\ \vdots \\ x_{d-1} \\ x_{d} \end{pmatrix} \otimes \begin{pmatrix} \cos m\theta_{1} \\ \cos m\theta_{2} \\ \cos m\theta_{2} \\ \vdots \\ \cos m\theta_{\frac{d}{2}} \\ \cos m\theta_{\frac{d}{2}} \\ \cos m\theta_{\frac{d}{2}} \end{pmatrix} + \begin{pmatrix} -x_{2} \\ x_{1} \\ -x_{4} \\ x_{3} \\ \vdots \\ -x_{d} \\ x_{d-1} \end{pmatrix} \otimes \begin{pmatrix} \sin m\theta_{1} \\ \sin m\theta_{1} \\ \sin m\theta_{2} \\ \sin m\theta_{2} \\ \vdots \\ \sin m\theta_{2} \\ \vdots \\ \sin m\theta_{\frac{d}{2}} \\ \sin m\theta_{\frac{d}{2}} \end{pmatrix}$$

$$\Theta = (\theta_{1}, \theta_{2}, ..., \theta_{d/2}) \text{ with:}$$

m is the token's position in the sequence.

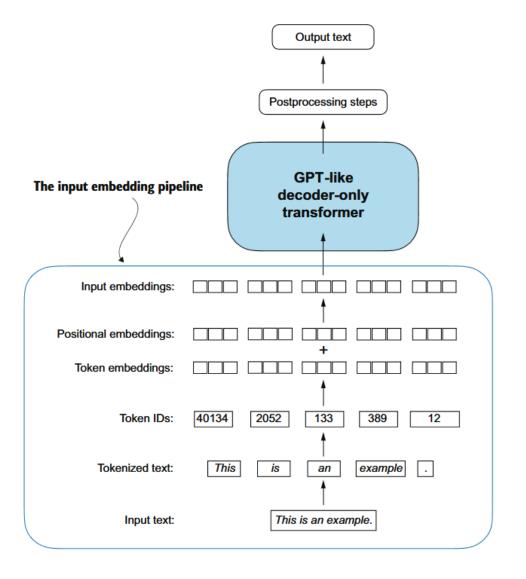

$$\Theta = (\theta_1, \theta_2, ..., \theta_{d/2})$$
 with:

$$\theta_i = 10000^{-2(i-1)/d}$$

Encoding word positions

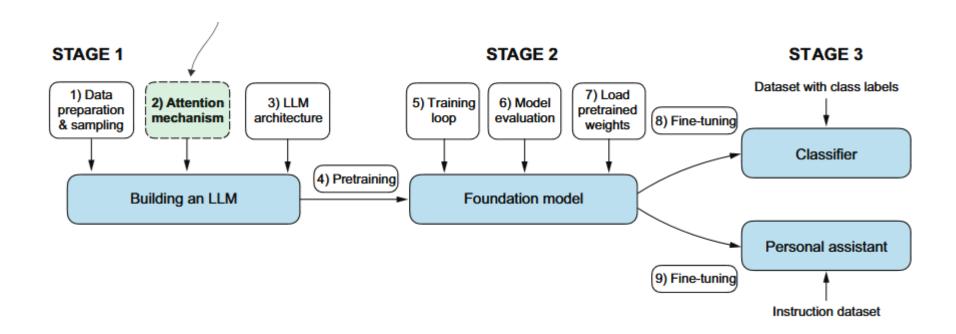

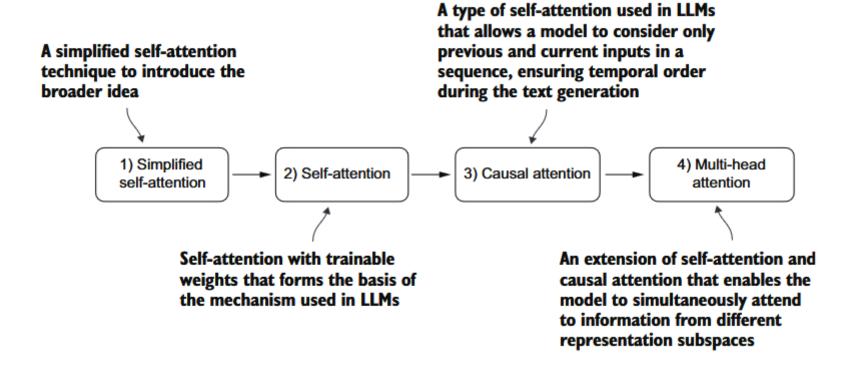

Attention mechanism

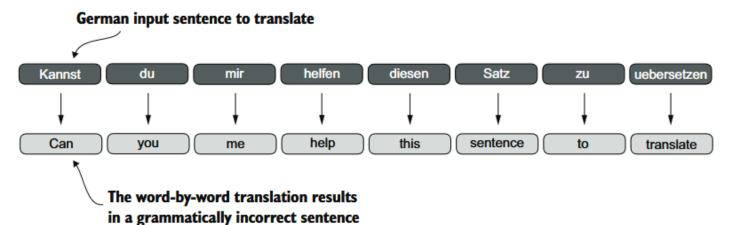

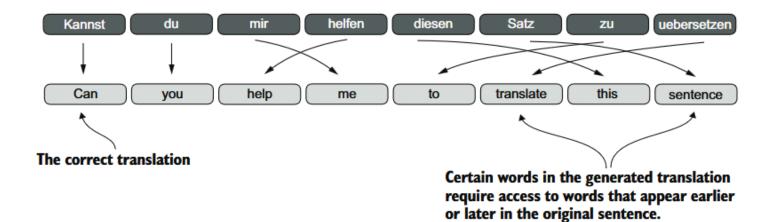

Problem with modeling long sequences

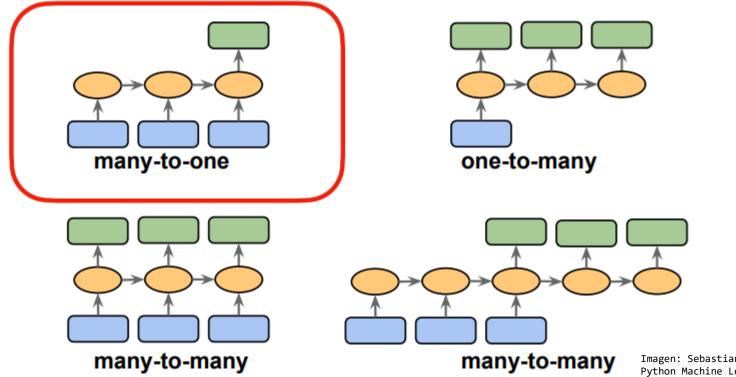

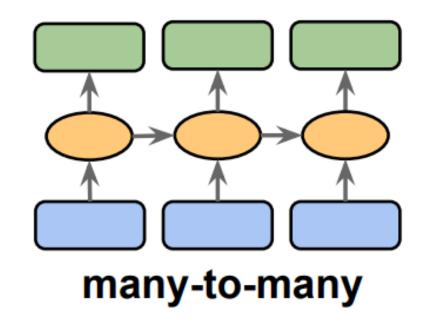

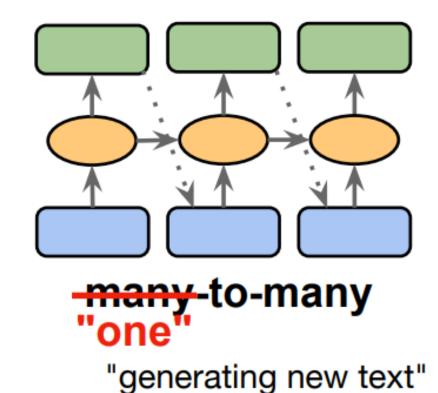

Imagen: Sebastian Raschka, Vahid Mirjalili.
Python Machine Learning. 3rd Edition.

Birmingham, UK: Packt Publishing, 2019

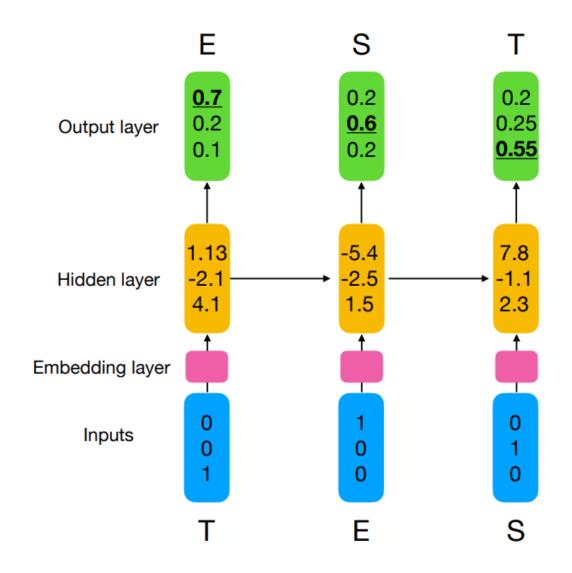

"training"

In RNNs, we asked about how backdrop through a network causes gradients can vanish or explode

$$\frac{dl}{d_{h_0}} = \text{tiny} \quad \frac{dl}{d_{h_1}} = \text{small} \quad \frac{dl}{d_{h_2}} = \text{med.} \quad \frac{dl}{d_{h_3}} = \text{large}$$

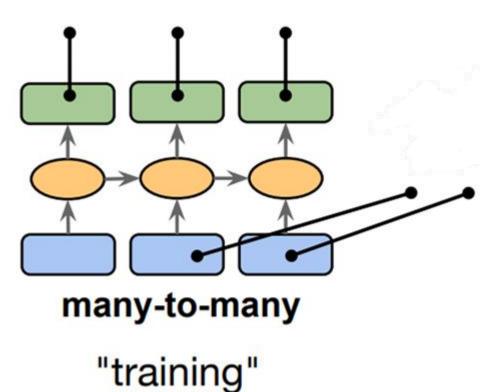

$$\begin{array}{c|c} \mathbf{h_0} & \mathbf{RNN} & \mathbf{h_1} & \mathbf{RNN} & \mathbf{h_2} & \mathbf{RNN} & \mathbf{h_3} & \mathbf{square_err} & \mathbf{b} \\ \hline \mathbf{x_1} & \mathbf{x_2} & \mathbf{x_3} & \mathbf{y}^* \end{array}$$

Recurrent Neural Networks

At each time step, Softmax output (probability) for each possible 'next letter

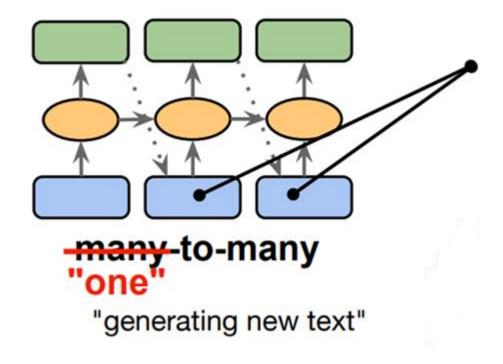

For the next input, ignore the prediction but use the 'correct' next letter from the dataset.

Recurrent Neural Networks

To generate new text, now display the softmax outputs and provide the letter as input for the next time step.

Long Short Term Memory Networks

Escuela de Ciencias Aplicadas e Ingeniería

https://pytorch.org/docs/stable/generated/torch.nn.LSTM.html

Parameters

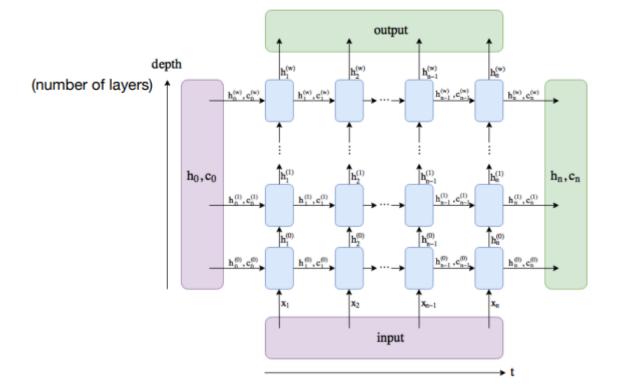

- input_size The number of expected features in the input x
- hidden_size The number of features in the hidden state h
- num_layers Number of recurrent layers. E.g., setting num_layers=2 would mean stacking two
 LSTMs together to form a stacked LSTM, with the second LSTM taking in outputs of the first LSTM
 and computing the final results. Default: 1
- bias If False, then the layer does not use bias weights b_ih and b_hh. Default: True
- batch_first If True, then the input and output tensors are provided as (batch, seq, feature).
 Default: False
- dropout If non-zero, introduces a Dropout layer on the outputs of each LSTM layer except the last layer, with dropout probability equal to dropout. Default: 0
- bidirectional If True, becomes a bidirectional LSTM. Default: False
- proj_size If > 0, will use LSTM with projections of corresponding size. Default: 0

```
>>> rnn = nn.LSTM(10, 20, 2)
>>> input = torch.randn(5, 3, 10)
>>> h0 = torch.randn(2, 3, 20)
>>> c0 = torch.randn(2, 3, 20)
>>> output, (hn, cn) = rnn(input, (h0, c0))
```

```
>>> rnn = nn.LSTM(10, 20, 2)
>>> input = torch.randn(5, 3, 10)
>>> h0 = torch.randn(2, 3, 20)
>>> c0 = torch.randn(2, 3, 20)
>>> output, (hn, cn) = rnn(input, (h0, c0))
```

https://pytorch.org/docs/stable/generated/torch.nn.LSTMCell.html

Inputs: input, (h_0, c_0)

- input of shape (batch, input_size): tensor containing input features
- h_0 of shape (batch, hidden_size): tensor containing the initial hidden state for each element in the batch.
- c_0 of shape (batch, hidden_size): tensor containing the initial cell state for each element in the batch.

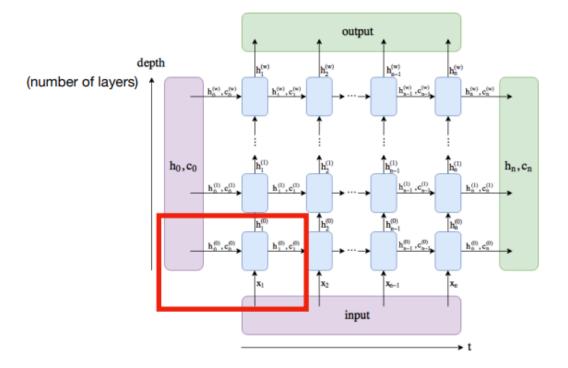

If (h_o, c_o) is not provided, both h_0 and c_0 default to zero.

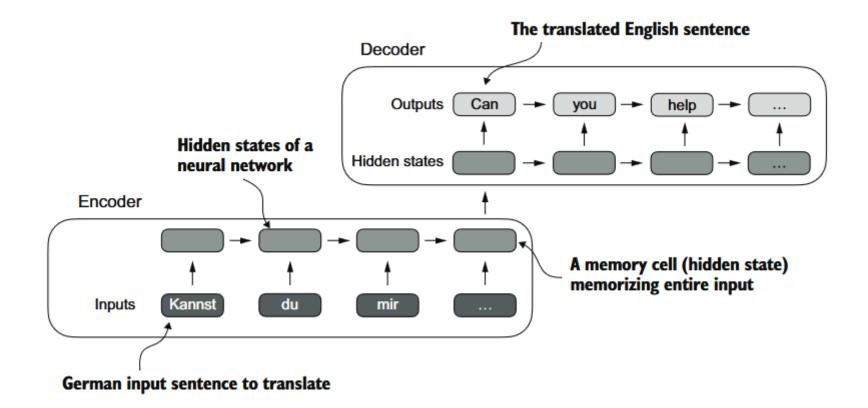

Outputs: (h_1, c_1)

- h_1 of shape (batch, hidden_size): tensor containing the next hidden state for each element in the batch
- c_1 of shape (batch, hidden_size): tensor containing the next cell state for each element in the batch

Attention mechanism

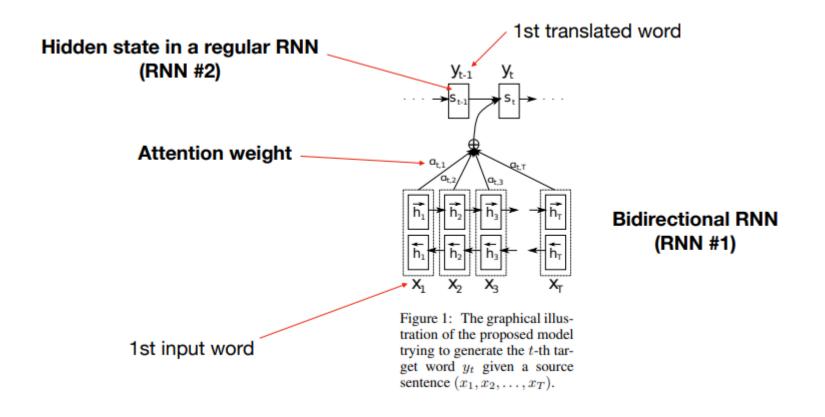

Assign an attention weight to each word to determine how much 'attention' the model should pay to each word (that is, for each word, the network learns a 'context').

Since ~2018, transformers have been growing in popularity... and size

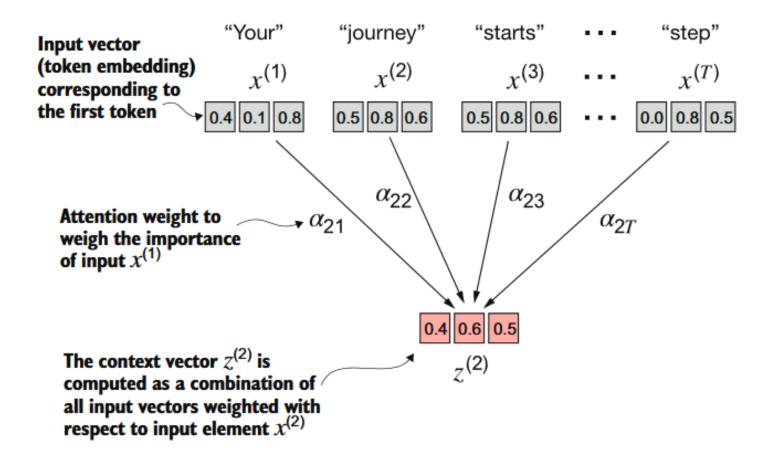

A simple self-attention mechanism without trainable weights

A simple self-attention mechanism without trainable weights

Escuela de Ciencias Aplicadas e Ingeniería

Self-attention as weighted sum:

$$\mathbf{A}_i = \sum_{j=0}^T a_{ij} \mathbf{x}_j$$

output corresponding to the i-th input

weight based on similarity between current input x_i and all other inputs

How to compute the attention weights?

here as simple dot product:

$$e_{ij} = \boldsymbol{x}_i^{\mathsf{T}} \boldsymbol{x}_j$$

repeat this for all inputs $j \in \{1...T\}$, then normalize

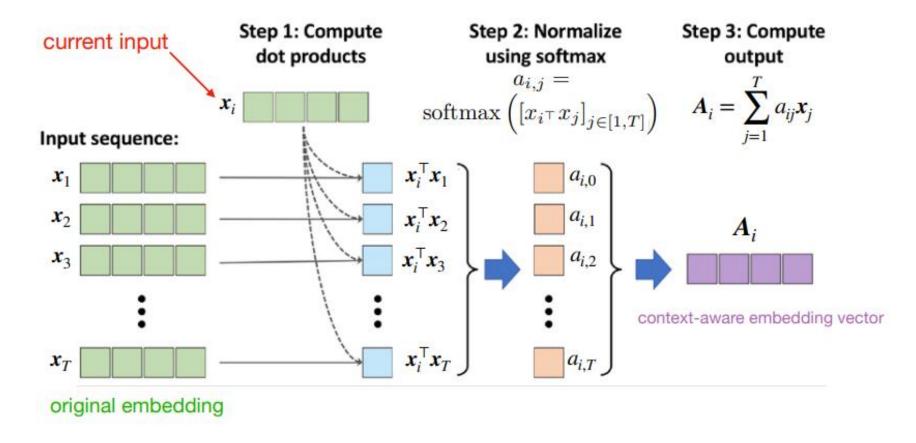

$$a_{ij} = \frac{\exp\left(e_{ij}\right)}{\sum_{j=1}^{T} \exp\left(e_{ij}\right)} = \operatorname{softmax}\left(\left[e_{ij}\right]_{j=1....T}\right)$$

A simple self-attention mechanism without trainable weights

Self-attention: Relating different positions within a single sequence (vs. between input and output sequences

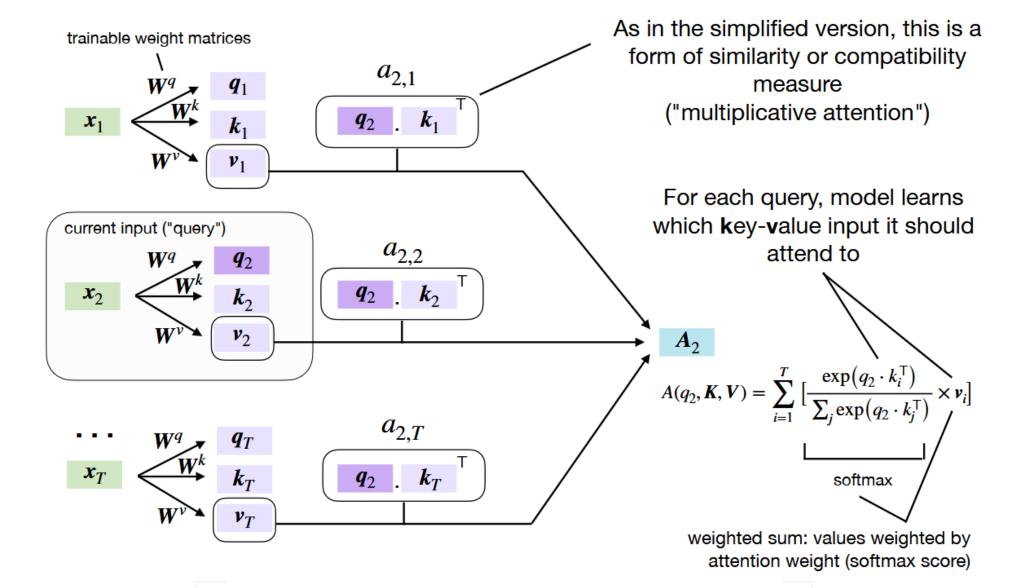

- Previous basic version did not involve any learnable parameters, so not very useful for learning a language model
- We are now adding 3 trainable weight matrices that are multiplied with the input sequence embeddings

query =
$$W^q x_i$$

key = $W^k x_i$
value = $W^v x_i$

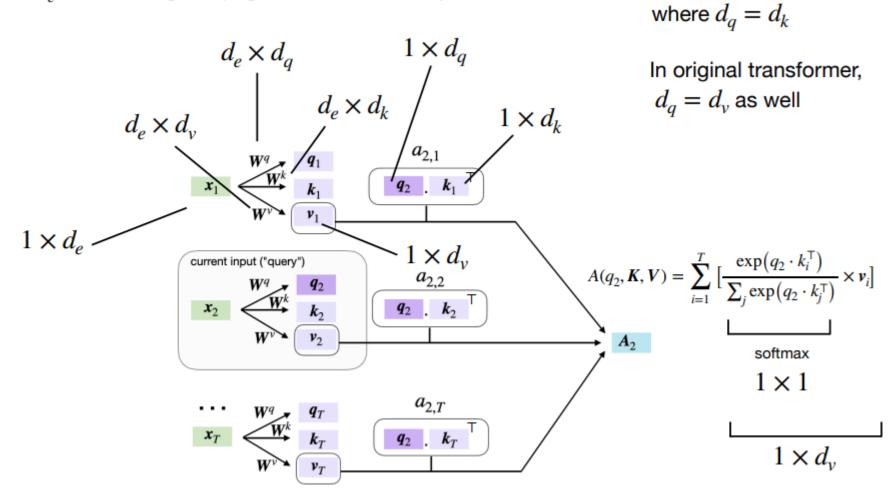

Escuela de Ciencias Aplicadas e Ingeniería

 d_e = embedding size (original transformer = 512)

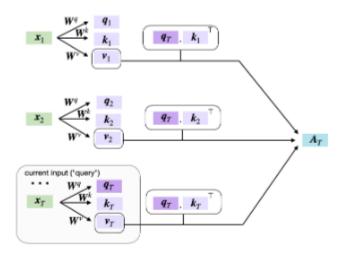

Self-attention mechanism

Attention score matrix: $A = \begin{bmatrix} A_1 \\ A_2 \\ A_3 \end{bmatrix}$

Self attention mechanism - Scaled dot producto attention

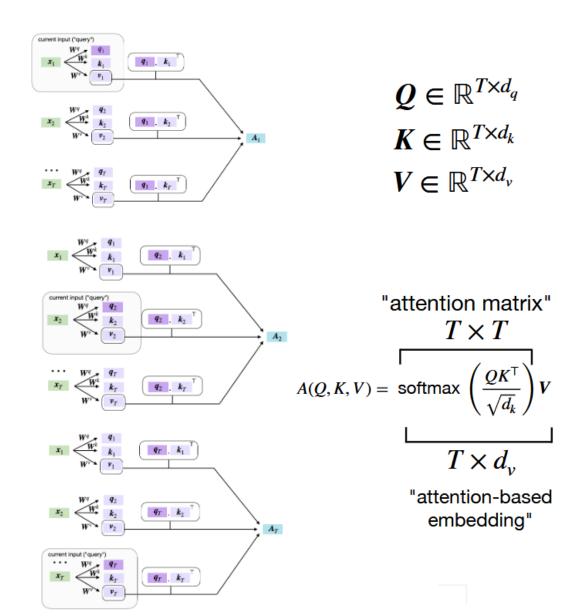

Escuela de Ciencias Aplicadas e Ingeniería

 $d_e = {
m embedding \ size}$

T = input sequence size

 $x \in \mathbb{R}^{T \times d_e}$

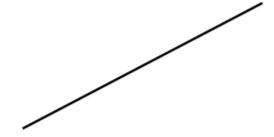

Scaled dot product attention

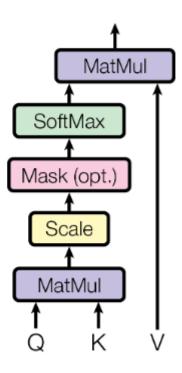

$$A(Q, K, V) = \text{softmax}\left(\frac{QK^{\mathsf{T}}}{\sqrt{d_k}}\right)V$$

To ensure that the dot-products between query and and key don't grow too large (and softmax gradient become too small) for large d_k

Scaled Dot-Product Attention

Vaswani, A., Shazeer, N., Parmar, N., Uszkoreit, J., Jones, L., Gomez, A.N., Kaiser, L. and Polosukhin, I., 2017. Attention Is All You Need.

Multi-Head attention

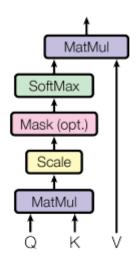

- Apply self-attention multiple times in parallel (similar to multiple kernels for channels in CNNs)
- For each head (self-attention layer), use different $W^q, W^k, W^v \, \text{then}$ concatenate the results $A_{(i)}.$
- 8 attention heads in the original transformer.
- Allows attending to different parts in the sequence differently.

Multi-Head attention

Scaled Dot-Product Attention

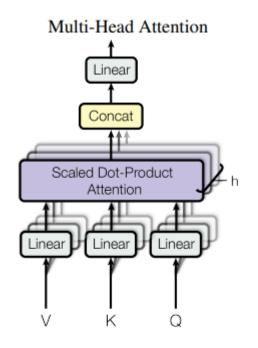

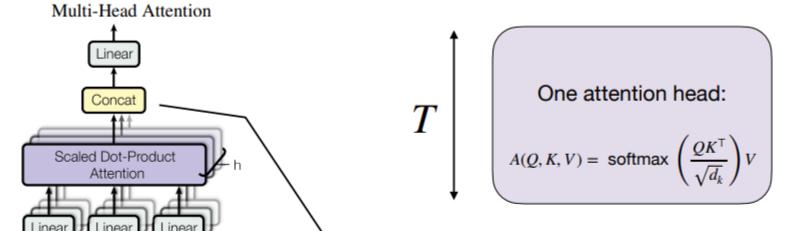

Figure 2: (left) Scaled Dot-Product Attention. (right) Multi-Head Attention consists of several attention layers running in parallel.

Layer Normalization

- Internal Covariate Shift occurs when the activation distributions of neurons change across training steps, forcing frequent weight adjustments.
- This phenomenon slows down training by causing instability in optimization.
- It happens when earlier layers undergo significant updates, leading to drastic changes in the inputs of subsequent layers.

$$y = rac{x - \mathbb{E}[x]}{\sqrt{ ext{Var}[x] + \epsilon}} \cdot \gamma + eta$$

- Batch Normalization normalizes across columns (features).
- Layer Normalization normalizes across rows (data items).

4 RMSNorm

A well-known explanation of the success of LayerNorm is its re-centering and re-scaling invariance property. The former enables the model to be insensitive to shift noises on both inputs and weights, and the latter keeps the output representations intact when both inputs and weights are randomly scaled. In this paper, we hypothesize that the re-scaling invariance is the reason for success of LayerNorm, rather than re-centering invariance.

We propose RMSNorm which only focuses on re-scaling invariance and regularizes the summed inputs simply according to the root mean square (RMS) statistic:

$$\bar{a}_i = \frac{a_i}{\text{RMS}(\mathbf{a})} g_i, \quad \text{where } \text{RMS}(\mathbf{a}) = \sqrt{\frac{1}{n} \sum_{i=1}^n a_i^2}.$$
 (4)

Intuitively, RMSNorm simplifies LayerNorm by totally removing the mean statistic in Eq. (3) at the cost of sacrificing the invariance that mean normalization affords. When the mean of summed inputs is zero, RMSNorm is exactly equal to LayerNorm. Although RMSNorm does not re-center

Residual Connections

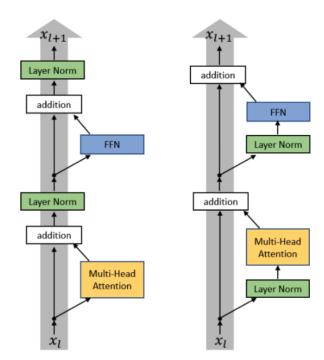

Add an additive connection between the input and output

$$Residual(\mathbf{x}, f) = f(\mathbf{x}) + \mathbf{x}$$

- Prevents vanishing gradients and allows f to learn the difference from the input
- Pre-layer-norm is better for gradient propagation

 Post-layer normalization

 Pre-layer normalization

Extract combination features from the attended outputs

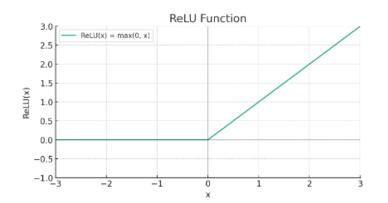

$$FFN(x; W_1, \mathbf{b}_1, W_2, \mathbf{b}_2) = f(\mathbf{x}W_1 + \mathbf{b}_1)W_2 + \mathbf{b}_2$$
